

METHODS OF SCIENTOMETRICS TO MODEL ACADEMIC CAREERS: A LITERATURE

REVIEW

Abstract¹

Scientometrics plays an increasing role in academic career analysis and evaluation. This process is "pushed" by rapid development of electronic databases as well as mathematics and network science and "pulled" by policy making analysis and career planners. In the last decades there has been a rapid proliferation of different indicators of researcher's productivity and influence. The traditional research method of personal-life academic productivity interaction is the CV and mobility analysis. Among the new methods of assessing academic careers, electronic databases offer a rapidly increasing set of personal data for analysis, and the opportunity to analyse the influences of different factors on academic performance. Moreover, statistical analysis of bibliometric data offers new possibilities to evaluate not just the personal, individual trajectories, but the importance of topics or institutional changes, too. In the future the agent based modelling, founded on databases or expert opinions, could be an important tool for estimation and forecast of different events on academic productivity. For this literature review a wide-range of relevant literature, 83 publications, has been used.

Key words: academic career, career research, academic performance.

1. Introduction

The classic, prevailing question of Hirsch (2005): "For the few scientists who earn a Nobel prize, the impact and relevance of their research is unquestionable. Among the rest of us, how does one quantify the cumulative impact and relevance of an individual's scientific research output?" (Hirsch 2005:16569). The academic career is the product

of the socio-economic-cultural background of a given society (or a set of societies, participating in the development of the personality and the career) and, on the other hand, an important vehicle of science. That is why this study is at the intersection of scientometrics, sociology and policy analysis. Analysis of careers in the field of science is gaining in importance and popularity, because the in-depth knowledge of mechanisms governing scientific career paths are important for planning and the realization of science policy, thereby increasing knowledge, economic and social output (Dietz 2000; Antonelli et al. 2011) and the science and technology (S&T) capacity as well as human capital (Bozeman – Rogers 2002). As Hirsch formulates it: "In a world of limited resources such quantification (even if potentially distasteful) is often needed for evaluation and comparison purposes (e.g., for university faculty recruitment and advancement, award of grants, etc.)" (Hirsch 2005:16569). Nevertheless, it is hard to answer the question of how to measure academic performance.

2. Research questions

Academic careers can be characterised on the basis of different sciences and approaches. One of the research questions is what the methods and tools for measuring academic performance are. Traditionally, academic performance can be measured by the number of (quality) publications and their impact on science, which is manifested in the number of citations (Van Balen – Leydesdorff 2009). This view of academic careers can be contested, because in the more "application-oriented" fields of science the number of publications is just one measure of academic performance. In high-tech industries the number of patents is a competing measurement dimension of academic performance. According to the traditional approach there is a strong correlation between the number of publications and the number of patents, but cointegration analysis, focusing on some rapidly advancing field of technology (e.g. the pharmaceutical industry) is not able to prove a statistically significant relation

¹ This paper based on a project that is receiving funding from the National Research, Development and Innovation Office (NKFI – K116163 – Career models and career advancement in research and development. Different patterns and inequalities in labour market opportunities, personal network building and work-life balance).

between the yearly number of publications and the number of patent applications in a given nation or research group. A further, more complex question is the efficiency of using the number of patent applications as a measurement. It is well-documented that just a very low share of patents will be applied in practice. In some fields, e.g. in plant production or animal husbandry, the number of new varieties of breeds could be applied as a measure of academic productivity.

If we accept measuring an academic career on the basis of the number of publications, it is a further problem how to measure academic performance: on the basis of the total number of papers during the lifetime, or on the basis of productivity per given time interval. Both measures offer some advantages and disadvantages; the time-based measures of academic productivity are capable of quantifying the regularity of authors. The time of determination of the end-point of an academic career leaves open one important question: whether the end of career is the publication of the last paper in the lifetime of the researcher should be at the time of retirement, and that all additional papers should be considered as a product of some hobby activity.

We will focus on the number of academic papers produced during the lifetime of the researchers, because these data lend themselves for a comparative approach, and if necessary a quantitative analysis can be performed. However, we have to take into consideration that this approach is a relatively narrow one: in future research a more holistic approach should be applied, taking into consideration other outputs, e.g. teaching activity, preparation of textbooks, as well as such activities as consulting, running spin-off companies or the popularisation of the sciences (Enders 2005; Glänzel – Debackere – Meyer 2007).

A considerable part of the publications on academic career apply an ontological approach, emphasizing the importance of the roots of academic careers. There is a wide consensus that the academic career is a product of a complex set of socio-economic factors. Some studies apply a more qualitative approach to this problem and try to grasp the motivational base and early results of academic careers by measuring the cultural capital of the family as well as the effect of narrower and wider socio-economic environment, emphasizing the influence of culture to publication behaviour and life strategy (van Balen et al. 2012; Leahey 2006).

Another important research question is the role different "vehicles" play in academic career. According to van Balen et al. (2012) and Wells et al. (2011) such individual factors, like cultural and social capital, results of effect of parents (Amarnani et al. 2016) and mentoring (Ehrich – Hansford – Tennent 2004) as well as networking will exercise a considerable impact on the development of academic careers. Another important factor of career development is the organisational environment, which could be measured by performance, prestige, or network position of the university (van Balen et al. 2012). In addition contextual factors, like labour market fluctuations should be taken into account, too. The overwhelming majority of the relevant publications have been written in the US, where a relatively high level of financial stability and individual mobility are a general condition. According to the experiences of some other countries (e.g. in crisis-hit European research centres or universities) these general conditions do not exist anymore, that is why the fluctuations in financial resources or the drying up of some sources for a given research activity could lead to the termination of an academic career (Figure 1).

3. Methods

The current investigation generally followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines (Moher et al. 2009).

3.1. Information Sources and Search

Literature searches were conducted in PubMed, Scopus, Web of Science, Scencedirect and Google Scholar. No limitations were placed on the dates of the searches, and the final search was completed in December 2016. After reviewing Scopus social subject headings for 'academic career' and 'scientific career', keywords selected for the search included research productivity, performance, success, patents, curriculum vitae, mobility, citation and collaboration. These keywords were combined with bibliometric, mathematics, scientometrics, research value mapping and social network analysis.

To find additional studies, the reference lists of the articles obtained were searched, as was the literature database of an investigator with extensive experience of academic career research.

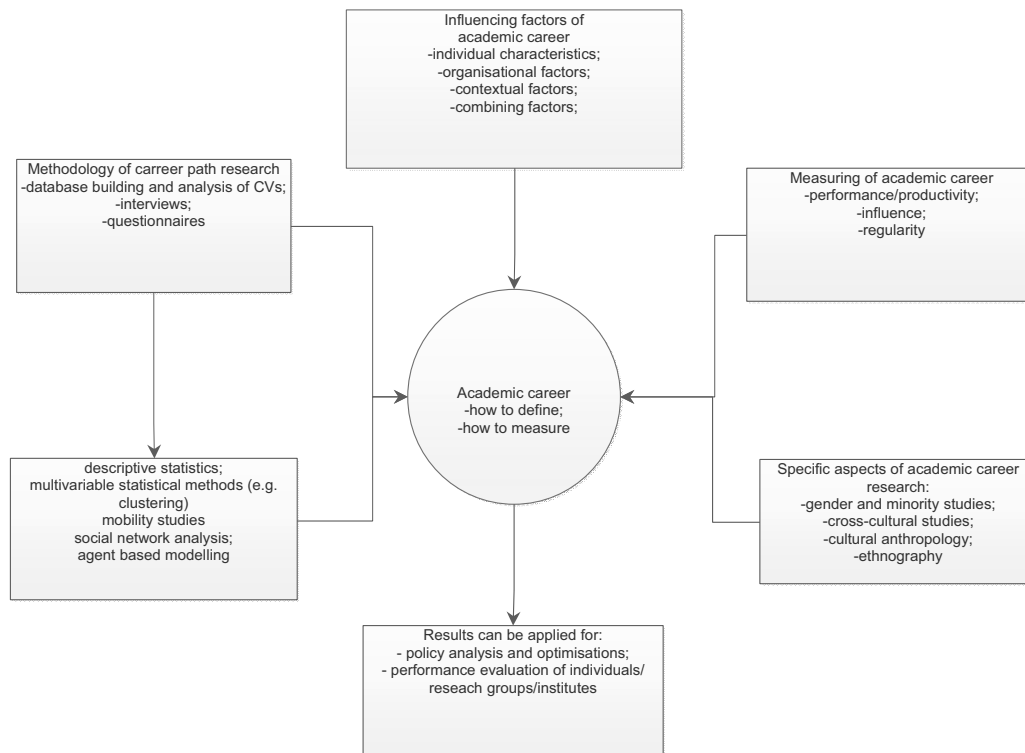

Figure 1 The "academic career puzzle"

3.2. Eligibility Criteria

Articles were selected for the review if they were (1) written in English, (2) involved bibliometric, mathematics or expositive methods to describe academic careers, and (3) provided a quantitative assessment. Titles were first examined and abstracts were reviewed if the article appeared to involve academic careers and either scientometrics or bibliometrics. The full text of the article was retrieved if there was a possibility that scientometrics analysis had been included within the investigation. Quantitative data could be contained within the text of the article, in tabular form, or presented in graphs. Data presented in graphic form were estimated. If the authors did not specifically aim to measure academic career, but data were available in the article to calculate it, then the article and the data were included in the review. Abstracts, case studies, and case series were not included. Stand-alone abstracts (without full-text articles) were excluded because they were difficult to locate, were generally not included in reference databases, and in many cases were not peer-reviewed. Case studies and case series involved few individuals and were often published because they were atypical.

4. Results

Figure 2 shows the number of publications included and excluded at each stage of the literature search. The initial search identified 21,694 citations, 5339 of which were duplicate publications (from different databases) that were removed. Based on a review of titles and abstracts, 345 full articles were obtained for review, and subsequently 135 were removed for not having relevance for research purposes or meeting the exclusion criteria. A total of 210 studies were further reviewed, but 127 of these did not contain either relevant or useful data. In total, 83 unique studies finally met the inclusion criteria.

4.1. The analysis of academic careers

It is widely recognized, that academic performance can be measured by two dimensions: overall productivity and the impact of works. According to Dietz and Boseman (2005) studies on academic careers often begin with the question as to why there seems to be a skewed distribution of research productivity across the population of academic sci-

Figure 2 Publications included and excluded at each stage of literature review

entists. In his seminal paper Lotka (1928), cited by Seglen (1992) highlighted that the vast majority of papers are published by a small minority of researchers. The vast majority of papers on this topic up to 1990s had been focusing on different sociological aspects of this question (Keith – Babchuk 1998). A considerable part of papers had been focusing on the sociological structures of science (Merton 1961), analysing science as a sociological entity. This approach considered science as an academic enterprise (Merton 1957, 1961), not taking into consideration the social embeddedness of science. In our opinion, this can be measured on the basis of publications, as opposed to some attempts (e.g. Dietz – Bozeman 2005) to try to involve the issue of patents into this topic. According to Baruch and Hall (2004) the academic career system has unique features, but empirical studies about academic careers are hardly available. Earlier studies have been conducted to model academic careers, but those were personal and introspective. Publications on academic career development are less focused on the development of the entire career. Balen et al. (2012) described which factors influence a successful academic career, the main question their paper aimed to answer was: Why do some talented researchers have a continued academic career, whereas others do not? The study was based on 42 semi-structured interviews; their results suggest that academic careers of talented researchers are stimulated or inhibited by an accumulation of advantages or disadvantages.

In the last decades, as a result of collaboration of bibliometricians, information scientists, sociologists, physicists and computer scientists, comprehensive science maps have been developed (Boyack – Klavans – Börner 2005). Guevara et al. (2016) developed the concept of *research space* as a more suitable approach for the evaluation of performance of individual researchers, teams or nations, because this is based on publication patterns of individuals. Table 1 shows studies on academic career separated by study design.

CV analysis

According to Dietz et al. (2000) CVs are particularly useful for the analysis of academic careers since they provide a complex picture of the life trajectory of researchers. Combined application of data collected from CVs and bibliographic measures improve data accuracy, help to avoid mismatches and offer valuable information to explain the changes in publication patterns and co-authors space. At the same time, Dietz et al. (2000) state that the analysis of curriculum vita to study career paths is an extremely difficult task, due to the hard quantification of different stages of individual lives. Their article offers a detailed description of ways and means to eliminate intercoder errors, and presents a model describing the effect of different factors on publication rate. Results prove a significant, positive regression coefficient (determined by

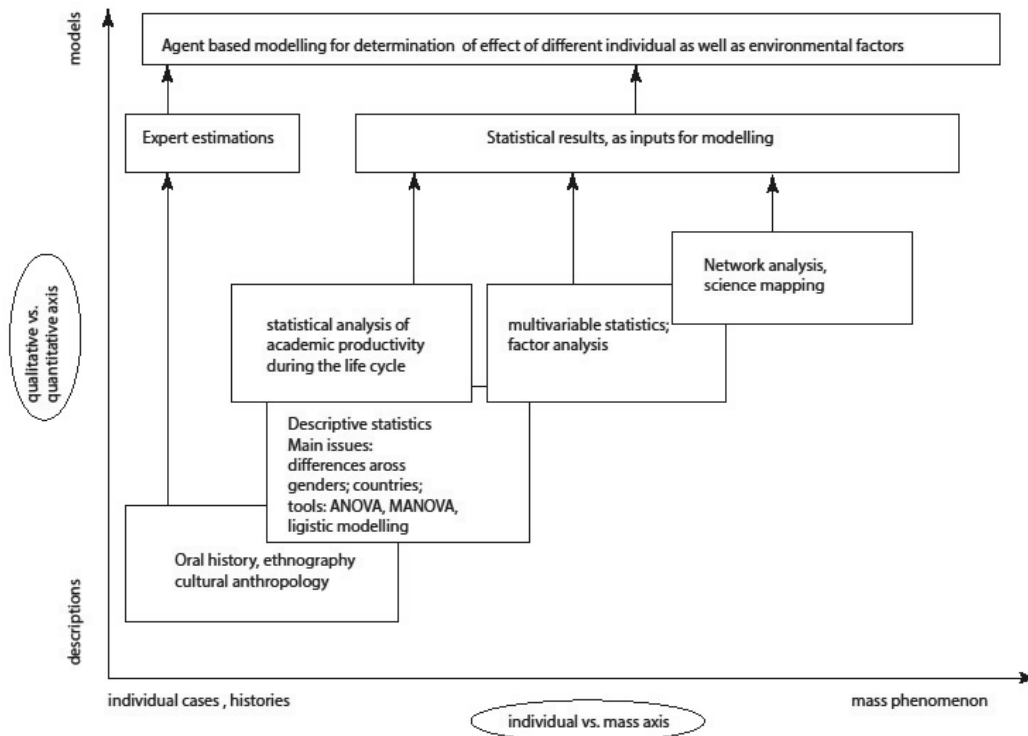

Figure 3 The field of application of different methods in career research

OLS) between the pre-PhD publications as well as the number of patents, and a negative coefficient in time of duration in the rank of assistant professor. The number of jobs has not been an important factor for productivity. In our opinion, the years spent as an assistant professor cannot be considered as an explanatory variable, because it could be rather a consequence of relatively low academic performance.

Statistical methods to measure academic career

Analysing the relevant literature, it is beyond doubt that there is a wide and ever increasing field of career research. This can be explained by the steadily increasing level of interest towards the problems of academic careers and the complexity of this question: this field of science lends itself to apply the tools and paradigms offered by different sciences. In figure 3 we have summarised the field of application of different methods in career research.

Development of databases

Recently there has been an important emergence of complex, unified, large-scale databases, offering the possibility of inter-individual as well as inter-institutional comparison in the analysis of academic careers on the basis of bibliometric data. As a result, we witness the birth of the science of science measurement (Lane 2010). Nowadays the two leading academic publication databases are the Web of Science and Scopus, but there is an increasing number of databases for geographic locations (e.g. Brazil: <http://lattes.cnpq.br/>; Hungary: <https://www.mtmt.hu/>).

Analysis of data on academic performance

The modern methods of scientometrical analysis apply statistical methods at an increasing rate. The rapid accumulation of information on citation patterns offers a favourable possibility to apply different statistical methods to citation patterns. Wallace – Larivière – Gingras (2009) have proven that the citations can be characterised

by a stretched-exponential function and a form of the Tsallis function to fit complete distributions over the 20th century. The Hirsch-core has been well known for more than a decade (Glänzel 2006) and Liang (2006) have introduced the h-index sequence for measuring the dynamics in a scientific career. According to their theory, the h index sequence h_k is the h-index of the papers published by the author in question in $n-k+1$, n time interval, where n is the most recent year. This is a logical continuation of Burrell's (2007) approach. According to their results (the h-index and its derivatives can be of great importance to track the life cycle of research teams. However there are considerable differences between averages of citations for one paper in different fields (e.g. according to Iglesias and Pecharrómán (2007) on the basis of ISI the expected number of citations for a paper in economics was 4.17 on average in the period between 1995–2005, the value of this indicator for molecular biology and genetics was 24.57). At the same time, while the wide-range of utilization of citation indices is fuelled by the fact that – as Radicchi – Fortunato – Castellano (2008) have proven – there is a universality of citation distributions across disciplines and years.

Modelling the patterns of individual academic trajectories

Petersen – Wang – Stanley (2010) offer normalised publication metrics to achieve a universal framework of analysing and comparing scientific achievement across both time and discipline. They have determined that the scaling exponent for individual papers ($\gamma \approx 3$) is larger than the scaling exponent for total citation shares ($\alpha \approx 2.5$) and that for total paper shares ($\alpha \approx 2.6$), which indicates that there is a higher frequency of stellar careers than stellar papers (Petersen et al., 2011). You – Han – Hadzibeganovic (2015) claim that in the field of science, from the point of view of quantitative analysis, there are two basic fields: (1) network-theoretic analysis and (2) soft-modelling of large datasets. They have applied an agent-based model to capture the most important aspects of publication and citation networks. In the model the agents were authors or research teams, and the nodes were the publications of citation networks. The inheritance process had been manifested

through the spread of citation relationships. In a subsequent publication Petersen et al. (2011) offer strong empirical evidence for universal statistical laws that describe career progress in competitive professions. The career paths can often be characterised by bimodal distributions: one class of careers is stunted by the difficulty in making progress at the beginning of a career. Based on the dynamics of publications they separate convex as well as concave progresses.

Petersen et al. (2011) have introduced the $N_i(t) \approx A_i [t(\exp \alpha_i)]$ temporal scaling relation, where α_i is a scaling exponent that quantifies the career trajectory dynamics. The estimation of α shows a relatively large similarity across disciplines; its value is between 1.3 and 1.44. According to Petersen et al. (2011) there is a possibility that short-term contracts may reduce the motivation for a young scientist to invest in human and social capital accumulation. As a summary, it can be stated, that there is an urgent need to group productivity measures, too.

The analysis of researchers' mobility and academic career

As is demonstrated in Figure 4, there are different approaches of career development analysis. A specific one is the analysis of *thematic mobility patterns*, based on *scientific mapping*. In the last decade, there was an effort to introduce some more quality-oriented methods into the evaluation of bibliometric data. That is why the g-index has been introduced by Egghe (2006). This index is the highest number of g of articles (a set of articles ordered by decreasing citation counts) that together received 2 or more citations. However, bibliometrics has more than half a century of tradition; its application shows considerable differences between disciplines and countries (Abbott et al. 2010). Notwithstanding, bibliometrics, as a science has Anglo-Saxon roots: many British, Commonwealth and US institutes use this for the evaluation of the performance of universities as well as research organisations, but in personal-related decisions the "soft" factors of personality evaluation (e.g. recommendation letters) are considered as more important factors. Sahel (2011) claims that the professional analysis of bibliometric data is important, but – in line with the recommendations of the French National Academy (FAS) – he discourages the application of

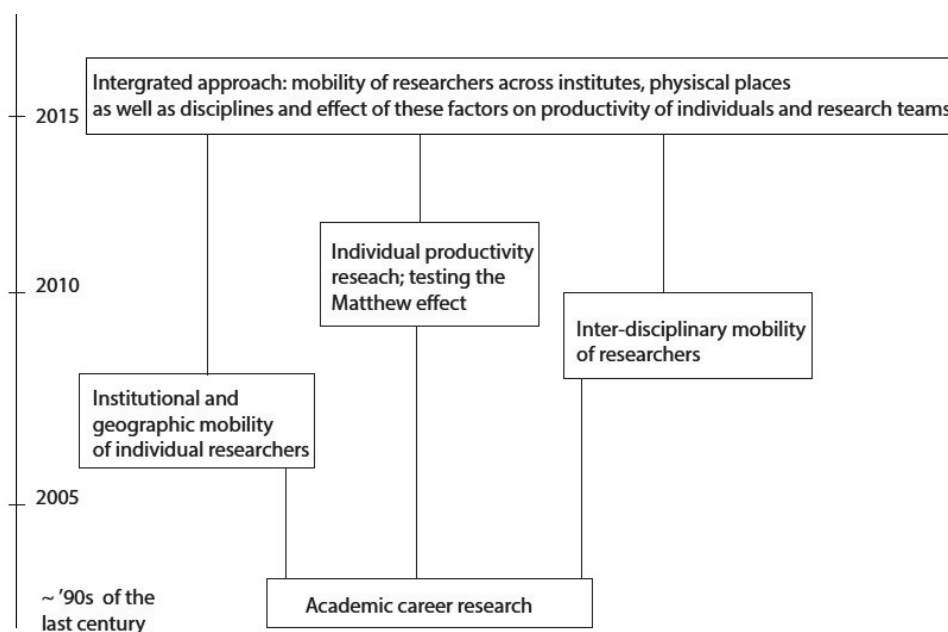

Figure 4: The different approaches of career development analysis

these data concerning personal decisions of young scientists.²

Workforce mobility has become a mainstream economic, political and media issue in the world during the last decade (Almeida – Kogut 1999; Nunn 2012). It is widely acknowledged that there is a strong relationship between competitiveness and the flexibility of the workforce, because workforce mobility between different sectors is a key factor of institutional mobility. Toffler – Nathan (1970) prediction that the pace of change in the world is increasing at a faster rate, and that this creates a more complex environment, leading to a more complex atmosphere for individuals as well as organisations (Toffer – Nathan 1970) is a reality today. It is well proven that social and geographical mobility as well as mobility within firms are necessary prerequisites for socio-economic analysis. Culié – Khapova – Arthur (2014) have determined a conceptual model for consequences of inter-firm collaborations on employment mobility. They em-

phasise the role of inter-firm collaborations in career capital-building, psychological mobility as well as analysing support. The mobility of academic staff was – and continues to be – of vital importance for the building of networks. According to Hauknes and Ekeland (2002) we can apply different methods in the area of mobility research. The differences reflect whether the population is static or dynamic; the time scale used and the basis of units used. The basic units of business demography are different. The most important categories are geographic location, ownership, employees, internal structure, and what is produced and how. The author remarks that "mainstream economic theory does not offer much help here". Most schools of economic thought generally take the firm as a given, unproblematic entity. Ladinsky (1967) have analysed the geographic migration patterns of professional workers. According to his results, professions that require heavy investments in capital equipment and close cultivation of clients can be described by low migration rates, salaried professions with short analysing hierarchies, and analysing work units have high migration rates, unstandardised work conditions, and strong occupational communication networks led to salaried workers in highly professional occupations moving on the national and regional level rather than in local labour markets. Sullivan and Arthur (2006)

2 FAS: L'Académie des sciences de l'Institut de France, Évaluation des chercheurs et des enseignants-chercheurs en sciences exactes et expérimentales: Les propositions de l'Académie des sciences. Available at: http://www.academie-sciences.fr/archivage_site/activite/rapport/rapport080709.pdf

have introduced the concept of *psychological mobility*, as "the perception of the capacity to make transitions". According to the findings of Geuna et al. (2015) there is a positive, significant effect of researchers' mobility on academic performance in the case of voluntarily mobile researchers both in the US and in GB. Mobility is a key factor in knowledge creation in different regions. Beside the favourable aspects of professional mobility the "inevitable disclosure" (2001) of trade secrets is a negative aspect of this phenomenon (Lincicum 2001).

European intellectual workforce mobility is promoted by the development of accreditation systems, the increasing role of multinational companies (Crescenzi – Pietrobelli – Rabellotti 2014), emergence of new human resource management practices and the decreasing importance of language barriers (Tenzer – Pudelko – Harzing 2014). Spilerman (1972) states that beside its computational simplicity the Markovian model is attractive because it is suitable for the description of different interrelationships as a system. Markovian chain models have been widely applied for the study of migration (Rogers, 1966) and projecting growth in social mobility (Erola – Moisis 2007) and manpower supply planning (Zanakis – Maret 1980). The sequence of events can be considered as a Markov chain if the outcome of each event is one of a set of discrete states and the outcome of an event depends only on the present state and not on any past states. The matrix, describing the probabilities of transition from one state to another, is called a transition matrix (Craig – Sendi 2002).

Research productivity

A considerable number of publications aim to analyse the differences between individual career paths. The most important of these are the analyses related to gender differences as well as to cross-cultural differences. The effect of children on academic productivity has been analysed by a linear growth model in an article by Hunter and Leahey (2010). They have determined that children have a negative effect on productivity over time. At the same time the authors acknowledge that their results are not generalisable.

Another measurement of academic productivity has been the application of the concept of *prestige*, applying different methods of *social network analysis* (Cole – Cole 1967; Reskin 1977; Long –

Allison – McGinnis 1979). A considerable number of papers have analysed academic careers as a series of state (position) changes, applying the approach of economic sociology and statistics (Markov models). Stephan and Levin (1992) applied an integrated model to research careers. On the basis of their work there are three drivers of academic careers: (1) intrinsic pleasure; (2) recognition and (3) reward. Put in another way: the triangle of the puzzle, the ribbon and the gold will determine an academic path. Lee et al. (2012) determine two components of career success: extrinsic and intrinsic success. In their seminal paper Dietz and Bozeman (2005) analysed the effects of job transformations and career patterns on productivity. The conceptual base of their research was built on Scientific & Technical human capital theory (Bozeman – Dietz – Gaughan 2001; Bozeman – Corley 2004). Based on the analysis of 1200 scientists' and engineers' CVs and publications, they set up a Tobit model in which the dependent variable was the number of publications per career year starting the year after the doctorate. Independent variables were the job homogeneity, precocity (measured by cumulative number of publications at the doctorate year, as well as numerous other characteristic features of academic career paths. According to their results there is a slightly positive association between career pattern homogeneity and publication productivity. Precocity and homogeneity both had a weak, positive relationship with publication rates.

5. Conclusions and recommendations for future research

There is considerable knowledge on the effect of different factors (prestige of the university, pre-Ph.D. publications, work abroad, birth of a child) on academic productivity. As a consequence, if we would like to evaluate the factors of academic careers, we have to analyse not just these factors, on a one-by-one basis, but also to take into account the combination of all of these influencing conditions. On the basis of this some typical career paths could be constructed. An agent-based simulation would be a suitable tool to model the effect of different "events" on academic productivity. It is rather hard to obtain quantifiable pieces of information on this topic because there is a great variability in individual "fate" and career, and it should be taken into consideration that there are considerable differenc-

es between different fields of science. That is why we suggest a series of expert interviews with the purpose to estimate the effect of different "events" on academic activity, based on the experiences of researchers. A convenient way of analysis of estimation results is the R-package "Expert" by Goulet – Jaques – Pigeon (2009). On the basis of these estimations a set of state charts could be constructed, serving as an input for agent based modelling. Such a high level software package (e.g. Anylogic) offers a favourable solution to the development of such a project aiming at forecasting the effects of different events on academic productivity.

Scientometrics and career research is a rapidly evolving field of science. Rapidly developing information systems, as well as archives, system dynamics, computer sciences and network analysis offer new possibilities for researchers from different scientific backgrounds to form inter- and multidisciplinary research teams. Based on our literature review, the most important problems of scientometrics and academic career research are as follows:

1. Influence of different events and shocks on academic productivity. How do changes in intellectual and material institutional

background influence the productivity in science?

2. Participation of scholars in science, as a self-organising network. It is widely acknowledged that there are some institutional and topical "hot spots" in science. Some people, depending on their level of ambitions, versatility of their qualification and personal background are more willing and able to "jump onto these band wagons", while some remain attached to their original field. Who are these people? Is a change of field a promising possibility to enhance one's scientific production?
3. The role of research-group attachment in academic career: it is well known, that the dynamically changing world makes it necessary to become attached to some research groups, which do some research together, then, in the framework of another project, a "recombination" takes place in the academic community and new teams are formed. Are there any patterns in these research team formations across countries and cultures?

Table 2 Estimation of the importance of academic productivity in the reviewed literature

Author	Year of publication	Target group	Method	Results
Dietz – Bozeman	2005	1200 US scientists and engineers	Tobit regression	Significant influence of Career Homogeneity index, Precocity; year of graduation important; held position, triple helix, first industry or governmental jobs; doctorates in biology or in computer science were not significant
Leahey	2006	Sociology (n=196) and linguistics (n=222) faculty members at US research universities	Structural equation modelling	Married family status (ever married) and affiliation to a public institution, as well as number of former institutions and receipt of research funding have significant, positive effect on performance. Gender, and PhD-granting institution ranking according to NRC is not significant
Chakraborty et al.	2014	DBLP dataset of the computer science domain (702,973 valid papers and 495,311 authors)	Stochastic model	The expertise of an author in a particular field is usually defined by the average number of citations received by the author by publishing papers in this field.
Fernández-Zubieta et al.	2013	171 UK academic researchers	Negative binomial regressions	There are positive albeit insignificant overall effects of mobility, and a negative weakly significant short-term effect. The mobility to a higher ranked university has only a weakly positive impact on publications output, but not on citations. The authors find no evidence that mobility per se increases academic performance.
Lindahl – Danell	2016	451 authors publishing on mathematical sub-field number theory	Univariate ROC analysis with multiple logistic regression analysis	The authors conclude that early career performance productivity has an information value in all tested decision scenarios, but future performance is more predictable in some cases.

Bentley	2011	Academic staff in Australian public universities, during the periods 1991–3 and 2005–7. Two surveys: a sample of 1420 and 1252 respondents.	Linear multiple regression	The proportion of variation in publication productivity accounted for by the 12-variable model (adjusted R-square) was 32% and 42% among men and women in the 1993 data, and 44% and 47% respectively in the 2007 data. Academic rank, doctorate qualifications, research time and international research collaboration were the strongest factors positively associated with publication productivity, but women typically reported significantly lower levels on each of these factors.
Petersen	2015	More than 166,000 collaboration records	Combination of descriptive and panel regression methods	Super ties contribute to above-average productivity and a 17% citation increase per publication, thus identifying these partnerships as a major factor in science career development. Strong collaborations have a significant positive impact on productivity and citations representing the advantage of “super” social ties characterized by trust, conviction, and commitment.
You et al.	2015	Two real-world citation datasets: The citation network of the American Physical Society (APS) journals and the condensed matter (Cond-mat) citation network of the arxiv.org online preprint repository	A multi-agent modeling framework	The work efficiency strongly affects agents’ academic outputs and impacts under a wide variety of conditions. Research direction selectivity plays a less important role, since the results indicate that a selection of hot research topics alone cannot provide sustainable academic careers under intensely competitive conditions.

Carvalho – Batty	2006	A total of 116,771 distinct authors with a U.S. address.	The productivity of U.S. research centres in computer science was highly skewed and the physical location of research centres in the U.S. formed a fractal set.
